STAT 2112 FINAL EXAM FORMULAE

Exponential Smoothing (F_t - forecasted value and A_t - actual value)

$$F_{t+1} = F_t + \alpha\left(A_t - F_t\right)$$

$$F_{t+1} = \alpha\, A_t + \alpha\left(1-\alpha\right) A_{t-1} + \alpha\left(1-\alpha\right)^2\, A_{t-2} + \alpha\left(1-\alpha\right)^3\, A_{t-3} + \ldots$$

Measuring Forecast Error

$$\text{MAD /MAE} = \sum_{t=1}^{T} \left| \text{ forecast error } \right| / T = \sum_{t=1}^{T} \left| \, A_t - F_t \, \right| / T$$

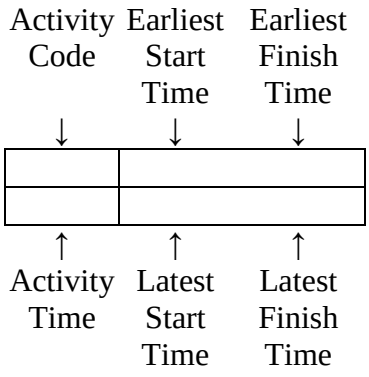
$$\text{MSE} = \sum_{t=1}^{T} \left| \text{ forecast error } \right|^2 / T = \sum_{t=1}^{T} \left| \, A_t - F_t \, \right|^2 / T$$

$$\text{MAPE} = 100 \sum_{t=1}^{T} \left[\, \left| \, A_t - F_t \, \right| / A_t \, \right] / T$$

PERT/CPM

The earliest start time for an activity is equal to the *largest* of the earliest finish times for all its immediate predecessors. The latest finish time for an activity is the *smallest* of the latest start times for all activities that immediately follow the activity.

Activity node:



Expected activity time : $t_i = \dfrac{a + 4m + b}{6}$

Activity variance: $\sigma_i^{\,2} = \left(\dfrac{b-a}{6} \right)^2$, where a is the optimistic time , b is the pessimistic time, and m is the most probable time.

The expected value of the total project time T, $E(T)$, is the sum of the expected times for the critical activities.

The variance in the project completion time, σ^2, is the sum of the variances of the critical activities.

z score: $z = \dfrac{x - \mu}{\sigma}$.

Inventory Model Notations

C_0 = Fixed cost per order

D = Annual number of items demanded

C = Unit cost of the inventory item

I = Annual holding cost rate

$C_h = IC =$ Cost of holding one item in inventory for one year

T = Time between orders

Q = Order quantity

C_b = Cost to maintain one unit on backorder for one year

Inventory Model without Backordering (Planned Shortages)

Optimal order quantity (economic order quantity, or EOQ): $Q^* = \sqrt{\dfrac{2DC_0}{C_h}}$.

Optimal time between orders: $T^* = \dfrac{Q^*}{D}$.

Total annual (relevant) cost: $TC(Q) = \left(\dfrac{D}{Q}\right)C_0 + C_h\left(\dfrac{Q}{2}\right)$.

Inventory Model with Backordering (Planned Shortages)

Optimal order quantity (economic order quantity, or EOQ): $Q^* = \sqrt{\frac{2DC_0}{C_h}\left(\frac{C_h + C_b}{C_b}\right)}$.

Maximum number of backorders: $S^* = Q^*\left(\frac{C_h}{C_h + C_b}\right)$.

Maximum on-hand inventory level: $Q^* - S^*$.

Total annual (relevant) cost: $TC(Q, S) = \frac{(Q-S)^2}{2Q}C_h + \frac{D}{Q}C_0 + \frac{S^2}{2Q}C_b$.
